The reliability of adult growth observations should be increased significantly in the future when the design of such experiments incorporates larger sample sizes. In this situation, the growth trends seen within a sample population will also suffer less from those individuals whose craniofacial features deviate considerably from the observed mean values. Considering its value as a predictive tool, knowledge of adult craniofacial growth in the coronal plane will be valuable.Â Behrents, R. A treatise on the continuum of growth in the aging craniofacial skeleton. Doctoral dissertation, University of Michigan, Ann Arbor, Michigan, 1984. Behrents, R. Growth in the Aging Craniofacial Skeleton. Craniofacial Growth Series, Ann Arbor, Michigan, 1985A. With its complex three-dimensional construction, the macroscopic effects of this remodeling are less easily interpreted for the aging craniofacial skeleton. The majority of the early work into the changes to skull shape with age consisted of cross-sectional approaches. This was achieved, for example, by comparing the dimensions of large numbers of dry skulls or making other qualitative observations from living subjects by various means, such as a lateral-head X-ray film measurement.

skeleton may be the primary cause for the manifestations of premature aging. These areas should be specifically examined in patients undergoing facial rejuvenation and addressed to obtain superior aesthetic results. Level of Evidence IV This journal requires that authors assign a level of evidence to each article. Selective bone resorption in the facial skeleton is not without precedent. Most notably, in the process of differential growth, areas of bone resorption occur adjacent to areas of bone deposition. Differential growth enables the infant skull to assume the proportions of the adult form [16, 17]. This process continues to remodel the fully dentate mature, facial bone and alters the craniofacial morphology into one that is instantly recognizable as an aged skull. 123.
