(by pressure-flaking or other methods) must also be considered in the analysis of artifact

Use-wear analysis takes into account the fact that repeated actions performed with a stone tool leave microscopic and sometimes macroscopic evidence of friction. These wear patterns and striations differ slightly depending on the material (wood, dirt, plant, bone, and meat) and the action (chopping, cutting, and abrading). Scientists have compared use-wear found on replicated tools used in experimental actions to use-wear found on artifacts. They have had success in classifying wear patterns found on artifacts. The high-powered use-wear analyses on five rejuvenation flakes indicates that all five pieces have worn edges once used in scraping and/or planing tasks. Four analyzed specimens were used on hard-high silica plant materials, and one on soft material such as hide. Residue analysis has become a frequently applied method for identifying prehistoric stone tool use. Residues adhering to the stone tool with varying frequencies are interpreted as being the result of an intentional contact with the worked material during use. We therefore argue for a closer interaction with independent wear studies and a step-wise procedure in which a low magnification of wear traces is used as a first step for selecting potentially used flakes in archaeological contexts. In addition, residue concentrations on a tool's edge should be sufficiently dense before linking them with use. Their first blind test [16] included 28 flaked stone tools, most of which were used, but some remained unused, or residues were intentionally applied to them.

**Stone Tools Description and Definition of Stone Tools:** Stone Tools were made of a variety of different stones, the preferred materials were primarily Flint and chert.
